

Many women suffer persistent pain after mastectomy

November 14 2013

Study suggests that psychological factors may be to blame.

(HealthDay)—Although breast cancer treatments have dramatically improved outcomes for women with the disease, ongoing pain continues to trouble many survivors long after they undergo a mastectomy, a new study finds.

In conducting the study, researchers examined 611 women who had a partial or total mastectomy to determine which factors contributed to their pain following the surgery. Those factors included [tumor size](#), stress or demographics. The women had also received chemotherapy and radiation with or without hormone therapy.

One-third of the women reported persistent pain in their breast, underarm, side or arm that had not improved in the three years following their surgery.

Researchers Dr. Inna Belfer, an associate professor of anesthesiology at the University of Pittsburgh, and her colleagues found no evidence that the type of mastectomy a woman had, the size of her tumor or treatment side effects were associated with pain following surgery, according to a journal news release.

Instead, certain psychological factors were implicated—with anxiety, depression and trouble sleeping linked to ongoing pain following a mastectomy.

The study also found that "somatization," or psychological distress that is expressed as [physical pain](#), was related to [persistent pain](#) after the procedure. The same held true for "catastrophizing," or a tendency to fixate about [pain](#) and feel unable to cope with it, the researchers said.

The study findings were published in a recent issue of the *Journal of Pain*.
