

Mysteries of childhood cognition studied

February 14 2007

U.S. scientists are trying to determine how children develop cognitive skills and how memory affects their judgments.

Researchers at the new Culture, Cognition, and Development Laboratory at Rutgers University-Camden say they are pursuing behavioral inquiries that will offer a deeper understanding of how children and adults perceive the world around them.

"How our minds develop as an interconnected part of our cultural worlds, from childhood throughout our adult lives, is infinitely complex," said assistant professor of psychology Sean Duffy. In one such study, Duffy provides evidence that children as young as five years of age rely upon statistical principles in order to increase the accuracy of their memories.

"For example, in remembering the height of a person you met last year, you combine inexact information about how tall the person actually was with information from the category of which that person is a member," he said.

"The statistical computations behind this are extremely complicated, and yet children as young as five show evidence that they use categories in the same way as adults, suggesting that this ability occurs at the start of life," said Duffy.

The research appeared in the journal *Developmental Science*.
