

# Red wine and grape juice help defend against food-borne diseases

October 11 2007

---

Red wine is known to have multiple health benefits. Researchers at the University of Missouri-Columbia have found that red wine may also protect humans from common food-borne diseases.

Researchers Azlin Mustapha, associate professor of food science in the College of Agriculture, Food and Natural Resources, and Atreyee Das, a doctoral student in the food science program, are conducting on-going studies examining the inhibitory effects of numerous types of red wines, as well as grape juice, against pathogens and probiotic bacteria, which naturally reside in the intestinal tract and can be beneficial in combating, among other things, high cholesterol and tumors.

They found that red wines – Cabernet, Zinfandel and Merlot in particular – have anti-microbial properties that defend against food-borne pathogens and don't harm naturally useful bacteria like probiotic bacteria.

*E. coli*, *Salmonella Typhimurium*, *Listeria monocytogenes* and *H. pylori* were among the pathogens examined. *E. coli* and *Listeria* can be fatal. Mustapha said the most promising results involved *Helicobacter pylori*, which can be transmitted via food and water and is the main cause of stomach ulcers.

“Our study is a little different than those previously reported in the media. Those studies promote moderate red wine consumption for cardiovascular diseases,” she said. “We went a step farther and asked: If

red wine is already good for cardiovascular diseases, what about food-borne pathogens" If you get a food-borne illness and drink red wine, will that help decrease the symptoms a little bit" This study showed that the four probiotics tested weren't inhibited by red wines; the pathogens were."

In lab tests, Mustapha and Das focused on ethanol, pH levels and resveratrol, which is a phytochemical found in grape vines and the skin of grapes. It also is responsible for the red coloring in red wines. They found that in addition to ethanol, pH and resveratrol also may inhibit food-borne pathogens.

Numerous white wines also were tested, but yielded no positive results, the researchers said.

"It's not just ethanol in the red wine that is inhibitory toward food-borne pathogens, but other factors which include the pH of the wine – because wines are a little acidic, and possibly the phytochemicals may have an effect," said Mustapha, noting that grape juice produces similar results. "We hypothesize that these phytochemicals, resveratrol being the main one, also play a role not just as antioxidants but also may have some inhibitions against food-borne pathogens. Now, we're concentrating mainly on the resveratrol effects on these pathogens."
