

Chronic Infection Now Clearly Tied to Immune-System Protein

June 13 2009

The reason deadly infections like human immunodeficiency virus (HIV) and hepatitis C never go away is because these viruses disarm the body's defense system. Researchers at the University of Alabama at Birmingham (UAB) have discovered that a key immunity protein must be present for this defense system to have a chance against chronic infection.

Research up to now has tried but failed to decipher the cross-talk between 'killer T-cells' and 'helper T-cells' in the fight against viruses. The new UAB study finds this cross-talk can only happen in the presence of interleukin-21, a powerful immune system [protein](#). If interleukin-21 is missing for whatever reason, then the immune system's anti-viral efforts fail, said Allan Zajac, Ph.D., an associate professor in UAB's Department of Microbiology and lead author on the study.

The findings are published in the journal *Science*.

"Adding interleukin-21 back in stimulates the immune response and controls the infection," Zajac said. "We demonstrate that the loss of this protein prevents the control of the infection and diminishes the function of the killer T-cells, specifically CD8 T-cells."

The study mice were treated for lymphocytic choriomeningitis, a viral infection of the membranes surrounding the brain and spinal cord. Measurements were taken for two types of T-cells, CD4 and CD8 T-cells, before and after the mice were treated with interleukin-21.

“Interleukin-21 served as the key messenger between the T-cells, whereas before we didn’t know exactly how the two types of cells communicated with each other,” Zajac said. The CD4 T-cells help the [immune system](#) do its job by boosting CD8 T-cells’ ability to fight and kill viruses.

Co-authors on the study include John Yi and Ming Du, Ph.D., both of UAB’s Department of Microbiology. Research funds came from the National Institutes of Health.
