

Antioxidant compound shows promising radioprotective properties

March 21 2011

Researchers at National Jewish Health have shown that an antioxidant compound can protect against injury to the lungs, gastrointestinal tract and the eye in a mouse model of acute exposure to ionizing radiation.

The compound, known as MnTE-2-PyP, is a form of metallopeptide antioxidant that is a more effective version of a naturally occurring antioxidant in the body known as superoxide dismutase. It is thousands of times more potent than [antioxidants](#) that are currently available in the United States.

As part of a \$9 million, five-year, grant from the US Department of

Defense, National Jewish Health researchers, led by James Crapo, MD, are currently collecting safety and efficacy data to enable an application for human clinical trials, and are also pursuing methods to synthesize pharmaceutical-grade MnTE-2-PyP.

MnTE-2-PyP is being developed as a protective agent against acute radiation exposure.

Ionizing radiation leads to the production of reactive oxygen species (ROS). These molecules cause damage to DNA, proteins, lipids, and ultimately, to tissue injury and death. Antioxidant therapy can be effective in reducing both the initial burst of ROS associated with [ionizing radiation](#) and in blocking or reducing the chronic ROS production and inflammatory cascade that mediates the radiation-induced tissue injury.
