

Study finds new genes that cause Baraitser-Winter syndrome, a brain malformation

February 29 2012

Scientists from Seattle Children's Research Institute and the University of Washington, in collaboration with the Genomic Disorders Group Nijmegen in the Netherlands, have identified two new genes that cause Baraitser-Winter syndrome, a rare brain malformation that is characterized by droopy eyelids and intellectual disabilities.

"This [new discovery](#) brings the total number of genes identified with this type of brain defect to eight," said William Dobyns, MD, a geneticist at Seattle Children's Research Institute. Identification of the additional genes associated with the syndrome make it possible for researchers to learn more about [brain development](#). The study, "De novo mutations in the actin genes ACTB and ACTG1 cause Baraitser-Winter syndrome," was published online February 26 in [Nature Genetics](#).

The [brain defect](#) found in Baraitser-Winter syndrome is a smooth brain malformation or "lissencephaly," as whole or parts of the surface of the brain appear smooth in scans of patients with the disorder. Previous studies by Dr. Dobyns and other scientists identified six genes that cause the smooth brain malformation, accounting for approximately 80% of affected children. Physicians and researchers worldwide have identified to date approximately 20 individuals with Baraitser-Winter syndrome.

While the condition is rare, Dr. Dobyns said the team's findings have broad scientific implications. "Actins, or the proteins encoded by the ACTB and ACTG1 genes, are among the most important proteins in the function of individual cells," he said. "Actins are critical for cell

division, cell movement, internal movement of [cellular components](#), cell-to-cell contact, signaling and [cell shape](#)," said Dr. Dobyns, who is also a University of Washington professor of pediatrics. "The defects we found occur in the only two actin genes that are expressed in most cells," he said. Gene expression is akin to a "menu" for conditions like [embryo development](#) or healing from an injury. The correct combination of genes must be expressed at the right time to allow proper development. Abnormal expression of genes can lead to a defect or malformation.

"Birth defects associated with these two genes also seem to be quite severe," said Dr. Dobyns. "Children and people with these genes have short stature, an atypical facial appearance, birth defects of the eye, and the smooth brain malformation along with moderate mental retardation and epilepsy. Hearing loss occurs and can be progressive," he said.

Dr. Dobyns is a renowned researcher whose life-long work has been to try to identify the causes of children's developmental brain disorders such as Baraitser-Winter syndrome. He discovered the first known chromosome abnormality associated with lissencephaly (Miller-Dieker syndrome) while still in training in child neurology at Texas Children's Hospital in 1983. That research led, 10 years later, to the discovery by Dobyns and others of the first lissencephaly gene known as LIS1.
