

Researchers find critical regulator to tightly control deadly pulmonary fibrosis

April 10 2012

An international team of researchers led by Georgia State University scientists have found a key component in the pathological process of pulmonary fibrosis, a fatal disease for which there is currently no cure.

The scientists found that a key [human gene](#), CLYD, serves as a crucial negative regulator in the development of the disease, halting its progression that leads to death. The research was published today in the journal *Nature Communications*.

"In some patients, CLYD does not function as it should or its [protein level](#) is lower than in normal individuals," said Jian-Dong Li, director of the GSU Center for Inflammation, Immunity and Infection (CIII) and Georgia Research Alliance (GRA) Eminent Scholar in Inflammation and Immunity.

"If this does happen, the [human tissue](#) repairing response can go out of control, leading to the development of fibrosis," added Li, senior author of the study and professor of biology at GSU.

According to the American Lung Association, about 140,000 Americans have been diagnosed with the disease. Patients' breathing symptoms worsen over time, and many patients live only three to five years after diagnosis.

There are currently no effective medicines available to [health care professionals](#) to cure [pulmonary fibrosis](#). Professionals can treat the

symptoms to reduce inflammation using steroids and [immunosuppressants](#), but there are serious side effects over time, including immune system suppression, which makes patients even more susceptible to infections.

"The disease often develops after infection or injury. In the case of infections brought on by [Streptococcus pneumoniae](#), a form of pneumonia, the body's immune system responds and tries to repair the damage, but in the case of fibrosis, this repairing process is overactive and causes scarring of the lungs," said Jae Hyang Lim, a GRA Distinguished Investigator and assistant professor at the CIII and Department of Biology.

The findings Li and his colleagues have presented have opened an exciting door to development of new therapeutics to fight the disease by aiming their sights on the CLYD gene.

"These results tell us that we now have a key regulator to target," said Binghe Wang, Director of the GSU Center for Diagnostics and Therapeutics and GRA Eminent Scholar in Drug Discovery and a co-author of the study.

"If we can target CLYD with a focus on regulating its protein level or activity, we may be able to better control fibrosis," said Wang, also chair of the Department of Chemistry at GSU. "There is a huge clinical potential in saving the lives of these patients."

The results are published in "CLYD Negatively Regulates Transforming Growth Factor- β Signaling via Deubiquitinating Akt," *Nature Communications*.

Li said the support provided by the GRA is invaluable to the groundbreaking research performed by scientists on the project. Li was

named as a GRA Eminent Scholar in 2010, and Lim came to Georgia State's CIII as a GRA Distinguished Investigator in 2011. Prior to Li and Lim, Wang was named as a GRA Eminent Scholar in 2003.

"These studies are collaborative, multi-disciplinary efforts," Li said. "The support from the GRA has allowed us to build state of the art facilities at Georgia State which have been essential to making this essential life-changing research possible."
