

Molecular 'on-off' switch for Parkinson's disease discovered

May 23 2012

(Medical Xpress) -- Scientists at the Medical Research Council (MRC) Protein Phosphorylation Unit at the University of Dundee have discovered a new molecular switch that acts to protect the brain from developing Parkinson's disease.

The findings have helped scientists understand how [genetic mutations](#) in a gene called PINK1 lead to Parkinson's in patients as young as 8 years old - which could eventually lead to new ways to diagnose and treat the condition.

The job of some proteins inside cells is to switch other important proteins on or off. Understanding how these proteins work and which proteins they target could be the key to why [nerve cells](#) die in Parkinson's - and how we can save them.

But despite intensive research, the target of the PINK1 enzyme (which is made by the PINK1 gene) has eluded scientists for almost a decade.

Now the Dundee team has found that PINK1 switches on a protein called [Parkin](#), whose main job is to keep cells healthy by removing damaged proteins. Mutations in the gene that makes Parkin can also cause inherited forms of Parkinson's in younger patients .

The team was led jointly by Dr Miratul Muqit and Professor Dario Alessi at the University of Dundee.

"Parkinson's is a devastating [degenerative brain disorder](#) and currently we have no drugs in the clinic that can cure or slow the disease down," said Dr Muqit, a Wellcome Trust Clinician Scientist in the MRC [Protein Phosphorylation](#) Unit.

"Over the last decade, many genes have been linked to Parkinson's but a major roadblock has been determining the function of these genes in the brain and how the mutations lead to brain degeneration."

Dr Muqit said, "Our work suggests this pathway can't be switched on in Parkinson's patients with genetic mutations in [PINK1](#) or Parkin. More research will be needed to see whether this also happens in Parkinson's patients who do not carry these mutations."

Professor Alessi, Director of the MRC [Protein](#) Phosphorylation Unit, added, "Now that we have identified this pathway, the key next step will be to identify the nature of these damaged proteins that are normally removed by Parkin. Although further studies are required, our findings also suggest that designer drugs that switch this pathway on could be used to treat Parkinson's."

The research was funded by the Medical Research Council, Wellcome Trust, Parkinson's UK, the J. Macdonald Menzies Charitable Trust and the Michael J. Fox Foundation.

The research is published in the latest edition of the journal *Open Biology*. The paper was co-authored with Dr Helen Walden from Cancer Research UK's London Research Institute.
