

New ruthenium-based drugs show promise for killing cancer cells

June 11 2012

A new study by University of Kentucky researchers shows how light and strained ruthenium-based drugs may be more effective at fighting cancer cells and less toxic to healthy cells than a similar and widely used drug.

Cisplatin is a common platinum-based cancer drug. But while cisplatin kills [cancer cells](#), it also attacks healthy cells, causing debilitating side effects. Ruthenium is a rare transition metal also belonging to the platinum group of the periodic table, and the UK researchers developed two new ruthenium complexes designed to kill cancer cells while preserving healthy cells.

These complexes are inert in the dark, but when activated with light, they become up to 200 times as toxic, and up to three times as potent as cisplatin against tumor cells.

Published in the [Journal of the American Chemical Society](#), the study examined the effects of these new complexes on lung cancer and [leukemia cells](#). Edith Glazer, UK assistant professor of chemistry and principal investigator for the study, hopes to move these compounds forward in more biological testing soon.

"Coordination chemistry has proven to be an elegant method to rapidly synthesize a family of molecules," Glazer said. "We anticipate that this will prove advantageous in allowing us to make chemical modifications to optimize properties as needed as we move forward into animal studies."
