Understanding immune response in these 'elite controllers' might help pave way to vaccine.

(HealthDay)—Researchers who discovered an immune system mechanism that seems to provide some people with a natural defense against HIV say their finding could help efforts to develop a vaccine for HIV/AIDS.

In most people, [HIV infection](#) without treatment almost always progresses to AIDS. But about one in 300 HIV-infected people remain AIDS-free without having to take medications. These people are called "elite controllers."

After conducting experiments with laboratory animals, the researchers

concluded that elite controllers suppress HIV by generating a powerful CD8+ T killer [cell response](#) against just two or three small regions of the virus.

"By focusing on these selected regions, the immune response successfully controls the virus," David Watkins, a professor of pathology at the University of Miami Miller School of Medicine, said in a university news release.

"Understanding this mechanism may shed light on how to develop an effective vaccine to eradicate the global HIV/AIDS crisis," he added.

Scientists, however, note that research with animals often fails to provide similar results in humans.

The study was published Sept. 30 in the journal *Nature*.

The next step is to determine why these particular [killer cells](#) are so effective, Watkins said.

Watkins and his colleagues recently received a \$10 million grant from the U.S. National Institute of Allergy and Infectious Diseases to develop an [HIV vaccine](#) from the yellow fever vaccine.
