

Toddlers' language skills predict less anger by preschool

December 20 2012

Toddlers with more developed language skills are better able to manage frustration and less likely to express anger by the time they're in preschool. That's the conclusion of a new longitudinal study from researchers at the Pennsylvania State University that appears in the journal *Child Development*.

"This is the first longitudinal evidence of early language abilities predicting later aspects of [anger](#) regulation," according to Pamela M. Cole, liberal arts research professor of psychology and human development and family studies at Pennsylvania State University, who was the principal investigator of the study.

Angry outbursts like temper tantrums are common among [toddlers](#), but by the time [children](#) enter school, they're expected to have more self-control. To help them acquire this skill, they're taught to use language skills like "using your words." This study sought to determine whether developing language skills relates to developing anger control. Does developing [language ability](#) reduce anger between ages 2 and 4?

Researchers looked at 120 predominantly White children from families above poverty but below middle income from the time they were 18 months to 48 months. Through home and lab visits, they measured children's language and their ability to cope with tasks that might elicit [frustration](#).

In one lab-based task, children were asked to wait 8 minutes before

opening a gift while their moms finished "work" (a series of questions about how the child usually coped with waiting). Children's anger and regulatory strategies were observed during the 8-minute wait. Among the strategies the children used were seeking support ("Mom, are you done yet?" or "I wonder what it is?") and distracting themselves from the gift (making up a story or counting aloud).

Children who had better language skills as toddlers and whose language developed more quickly expressed less anger at age 4 than their peers whose toddler language skills weren't as good. Children whose language developed more quickly were more likely to calmly seek their mother's support while waiting when they were 3, which in turn predicted less anger at 4. Children whose language developed more quickly also were better able to occupy themselves when they were 4, which in turn helped them tolerate the wait.

"Better [language skills](#) may help children verbalize rather than use emotions to convey needs and use their imaginations to occupy themselves while enduring a frustrating wait," according to Cole.
