

Why makeup matters? Psychology reveals new sign of aging in perception research

March 17 2013, by Kendra Martin

Russell researching facial perception

(Medical Xpress)—The contrasting nature of facial features is one of the signals that people unconsciously use to decipher how old someone looks, says Psychology Prof. Richard Russell, who has been collaborating with researchers from CE.R.I.E.S. (Epidermal and Sensory Research and Investigation Center), a department of Chanel Research and Technology dedicated to skin related issues and facial appearance.

"Unlike with [wrinkles](#), none of us are consciously aware that we're using this cue, even though it stares us in the face every day," said Russell.

The discovery of this cue to facial age perception may partly explain why cosmetics are worn the way they are, and it lends more evidence to the idea that [makeup](#) use reflects our biological as well as our [cultural heritage](#), according to Russell.

In one study, Russell and his team measured images of 289 faces ranging in age from 20 to 70 years old, and found that through the [aging process](#), the color of the lips, eyes and [eyebrows](#) change, while the skin becomes darker. This results in less contrast between the features and the surrounding skin – leaving older faces to have less contrast than younger faces.

Facial contrast image

The difference in redness between the lips and the surrounding skin

decreases, as does the luminance difference between the eyebrow and the forehead, as the face ages. Although not consciously aware of this sign of aging, the mind uses it as a cue for perceiving how old someone is.

In another study involving more than a hundred subjects in Gettysburg and Paris, the scientists artificially increased these facial contrasts and found that the faces were perceived as younger. When they artificially decreased the facial contrasts, the faces were perceived as older.

The image shows two identical images of the same face, except that the facial contrast has been increased in the left image and decreased in the right image. The face on the left appears younger than the one on the right.

Cosmetics are commonly used to increase aspects of facial contrast, such as the redness of lips. Scientists propose that this can partly explain why makeup is worn the way that it is – shades of lipstick that increase the redness of the lips are making the face appear younger, which is related to healthiness and beauty.

More on Russell's [study is available](#) from *PLOS ONE*.
