

Decision support system improves ADHD diagnosis

August 21 2013

Use of a clinical decision support module results in higher quality of attention-deficit/hyperactivity disorder diagnosis, according to a study published online Aug. 19 in *Pediatrics*.

(HealthDay)—Use of a clinical decision support module results in higher quality of attention-deficit/hyperactivity disorder (ADHD) diagnosis, according to a study published online Aug. 19 in *Pediatrics*.

Aaron E. Carroll, M.D., from Indiana University in Indianapolis, and colleagues conducted a cluster randomized [controlled trial](#) in which the diagnosis and management of ADHD in 6- to 12-year-olds (84 children) were compared before and after implementation of a computer [decision support system](#) in four practices.

The researchers found that the use of structured diagnostic assessments dropped from 50 percent in the baseline period to 38 percent in the

intervention period in the [control group](#), while it rose in the intervention group from 60 to 81 percent. Even after controlling for age, gender, and race, the difference was statistically significant (odds ratio of structured diagnostic assessment in intervention group versus control group, 8.0). The number of ADHD core symptoms noted at the time of diagnosis was also significantly different between the groups. The percentage of patients who had documented medication adjustments, mental health referrals, and visits to mental health specialists was higher in the [intervention group](#) than the control group, although the study was not powered to detect changes in care and management.

"The introduction of a clinical decision support module resulted in higher quality of care with respect to ADHD diagnosis including a prospect for higher quality of ADHD management in children," the authors write.
