Memory about a core item (such as a word, object, or picture) is called item memory while memory about the context or related features of a core item is defined as source memory. What determines which sources within an episode are successfully remembered is of particular interest to researchers. Behavioral evidence suggests that the orientation of a memory task influences whether the related source of the item will be remembered later.

A study by Prof. Xiuyan Guo and colleagues from East China Normal University, China explored changes in the hippocampus and [prefrontal cortex](#) while participants completed two tasks: an item-oriented task and a source-oriented task. The researchers found that subsequent source

memory effects in the right prefrontal cortex and hippocampus were modulated by task orientation, whereas task orientation modulated item [memory](#) effects in the prefrontal cortex.

These findings, published in the *Neural Regeneration Research* (Vol. 8, No. 26, 2013), highlight the possibility that the [hippocampus](#) contributes to the intentional encoding of item-source associations, whereas the prefrontal cortex is biased toward processing information to which attention is directed.
