

Discovery may lead to new treatments for allergic diseases

November 11 2013

(Medical Xpress)—A collaboration among researchers in Israel and the United States has resulted in the discovery of a new pathway that has broad implications for treating allergic diseases – particularly eosinophil-associated disorders.

The researchers from Tel Aviv University and Cincinnati Children's Hospital Medical Center have discovered how this pathway kills eosinophils before they can cause havoc. Eosinophils are normal cellular components of the blood, but when the body produces too many eosinophils they can cause a variety of eosinophilic disorders. These are disorders involving chronic inflammation resulting in tissue damage, often in the gastrointestinal system.

The study is published online in the journal *Nature Immunology*.

"The fundamental knowledge we have gained may one day yield new therapies to treat devastating eosinophilic disorders," says Ariel Munitz, PhD, a researcher at the department of Clinical Microbiology and Immunology at the Sackler School of Medicine at Tel Aviv University and corresponding author of the study.

Eosinophils are regulated by interleukin 5 (IL-5), a protein that triggers eosinophils to leave the bone marrow and enter the bloodstream, where they can reach various organs. Dr. Munitz and Marc Rothenberg, MD, PhD, director of Allergy and Immunology at Cincinnati Children's, have identified a pathway for counterbalancing what happens when IL-5

triggers eosinophils. The newly identified pathway involves a key checkpoint controlled by a pair of proteins, PIR-A and PIR-B, which the researchers now show have a critical role in eosinophil development.

PIR-A induces eosinophils to die and thus is in a perpetual tug-of-war with survival and growth signals driven by IL-5. The researchers discovered that PIR-A is dominant in this battle but that cell death doesn't occur because PIR-B inhibits its actions. For PIR-A to win the battle and cause cells to die, PIR-B must be shut down.

The researchers studied asthmatic mice and discovered that asthmatic mice without PIR-B had little expansion of eosinophils in their blood and lungs and less asthmatic inflammation in their lungs than normal mice. The lack of PIR-B kept eosinophils from reaching harmful levels. The researchers hope that scientists can now target PIR-A to enhance its ability to kill [eosinophils](#) or weaken PIR-B so that it inhibits PIR-A to a lesser extent.

The study was led by Netali Baruch-Morgenstern and Dana Shik from the Munitz lab. They are graduate students at Tel Aviv University who spent part of their training in Dr. Rothenberg's lab at Cincinnati Children's. Dr. Munitz is a former research fellow in Dr. Rothenberg's lab.

The study was funded in part by a grant from the United States-Israel Binational Science Foundation (grant number 2009222), which promotes scientific relations between the U.S. and Israel by supporting collaborative research projects in a wide area of basic and applied scientific fields.

Funding also came from the FP7 Marie-Curie Reintegration grant (grant number 256311), the Israel Science Foundation (grant numbers 955/11 and 1708/11), the Israel Cancer Research

Foundation Research Career Development Award, the Fritz Thyssen Foundation, the US-Israel Bi-national Science Foundation, the National Institute of Allergy and Infectious Diseases, (R01AI083450, R37AI045898), CURED Foundation, FARE, and Buckeye Foundation.

The study also is the result of the Israel Exchange Program (IEP) at Cincinnati Children's. Through the IEP, Cincinnati Children's collaborates with leading Israeli institutions to improve clinical care for children, train pediatric providers and researchers, advance scientific research and make technological breakthroughs that benefit children throughout the world.

More information: Paired immunoglobulin-like receptor A is an intrinsic, self-limiting suppressor of IL-5–induced eosinophil development, [DOI: 10.1038/ni.2757](https://doi.org/10.1038/ni.2757)
