

World's smallest, leadless heart pacemaker implanted at Ohio State

May 6 2014

Dr. John Hummel (left) and Dr. Ralph Augostini of The Ohio State University Wexner Medical Center are among the first in the U.S. to implant the world's smallest pacemaker. Roughly half the size of a AAA battery, the pacemaker is designed to monitor the patient's heart and only activate when needed. It is expected to last up to 14 years. It's about the size of a large vitamin pill and, for the first time in Ohio, the smallest heart pacemaker available is being tested at The Ohio State University Wexner Medical Center.

Doctors at Ohio State's Richard M. Ross Heart Hospital recently implanted the tiny device in a Columbus woman as part of a global clinical trial to test its safety and effectiveness. Unlike conventional pacemakers, which require a chest incision and electrical leads that run through a vein to the heart, this device is wireless and is threaded through a catheter, then attached directly to the heart muscle.

"With this investigational device, the battery, the pacing electrodes, everything is in a little piece of metal sitting inside the heart. We believe that will eliminate a lot of risk for infection and complications," said Dr. John Hummel, a cardiologist and principal investigator of the trial at Ohio State.

If this transcatheter, leadless pacemaker technology works the way doctors hope, they say it could not only benefit patients, but the minimally invasive approach would be more efficient.

"I think this could be a significant development in pacing procedures. This could cut our procedure time by more than half," said Dr. Ralph Augostini, a cardiologist at Ohio State.

Doctors at The Ohio State University Wexner Medical Center use a catheter to place a tiny, high-tech pacemaker directly into the heart of Mary Lou Trejo, 77, of Columbus, Ohio. The pacemaker is 90 percent smaller than traditional pacemakers and because it has no leads that are fed from the upper chest into the heart, doctors say the risk of infection and complications could be cut dramatically. For now, the tiny pacemaker is being tested in people with bradycardia who need single chamber ventricular pacing. Bradycardia is a slow, <u>irregular heart rhythm</u> which prevents the heart from pumping enough blood into the body. This can cause fatigue, dizziness, shortness of breath and fainting.

A former librarian, 77-year-old Mary Lou Trejo of Columbus, had been suffering from atrial fibrillation for years. Her <u>heart</u> had slowed, despite medication and other treatments to restore rhythm, so she was eager to be among the first in the United States to participate in this clinical trial.

"The new pacemaker sounded so simple, and I have always thought

research is important, so I thought this is a way I could contribute," Trejo said.

The trial will enroll 780 patients in 50 centers worldwide. Investigators are expected to report initial results later this year, once the first 60 patients have been followed for three months.
