

# In search for Alzheimer's drug, a major STEP forward

August 5 2014

---

Researchers at Yale School of Medicine have discovered a new drug compound that reverses the brain deficits of Alzheimer's disease in an animal model. Their findings are published in the Aug. 5 issue of the journal *PLoS Biology*.

The compound, TC-2153, inhibits the negative effects of a protein called STriatal-Enriched tyrosine Phosphatase (STEP), which is key to regulating learning and memory. These cognitive functions are impaired in Alzheimer's.

"Decreasing STEP levels reversed the effects of Alzheimer's disease in mice," said lead author Paul Lombroso, M.D., professor in the Yale Child Study Center and in the Departments of Neurobiology and Psychiatry at Yale School of Medicine.

Lombroso and co-authors studied thousands of small molecules, searching for those that would inhibit STEP activity. Once identified, those STEP-inhibiting [compounds](#) were tested in brain cells to examine how effectively they could halt the effects of STEP. They examined the most promising compound in a mouse model of Alzheimer's disease, and found a reversal of deficits in several cognitive exercises that gauged the animals' ability to remember previously seen objects.

High levels of STEP proteins keep synapses in the brain from strengthening. Synaptic strengthening is a process that is required for people to turn short-term memories into long-term memories. When

STEP is elevated in the brain, it depletes receptors from synaptic sites, and inactivates other proteins that are necessary for proper cognitive function. This disruption can result in Alzheimer's disease or a number of neuropsychiatric and neurodegenerative disorders, all marked by cognitive deficits.

"The small molecule inhibitor is the result of a five-year collaborative effort to search for STEP inhibitors," said Lombroso. "A single dose of the drug results in improved cognitive function in mice. Animals treated with TC compound were indistinguishable from a control group in several cognitive tasks."

The team is currently testing the TC compound in other animals with cognitive defects, including rats and non-human primates. "These studies will determine whether the compound can improve cognitive deficits in other animal models," said Lombroso. "Successful results will bring us a step closer to testing a drug that improves cognition in humans."
