

# APOE, diagnostic accuracy of CSF biomarkers for Alzheimer's disease

August 27 2014

---

Cerebral spinal fluid (CSF) levels of  $\beta$ -amyloid 42(A $\beta$ 42) are associated with the diagnosis of Alzheimer's disease (AD) and (A $\beta$ ) accumulation in the brain independent of apolipoprotein E (APOE) gene makeup.

With the emergence of biomarker dementia diagnostics, interest in CSF biomarkers associated with AD, including A $\beta$ 42 and tau proteins, is increasing. The APOE gene is the most prominent susceptibility gene for late-onset AD. For the best clinical use of genetic and CSF biomarkers, studies are needed to clarify to what extent the APOE genotype and CSF biomarkers are related and if they provide overlapping vs. complementing information for the diagnosis and prognosis of AD and whether different clinical cutoffs for CSF levels of A $\beta$ 42 should be used depending on the APOE genotype.

The author examined whether APOE genotype affects the diagnostic accuracy of CSF biomarkers for AD, in particular A $\beta$ 42 levels. They used data from four centers in Sweden, Finland and German and had three different study groups. Cohort A included 1,345 people (ages 23 to 99 years) with baseline CSF levels, including 309 individuals with AD, 287 with prodromal (mild) AD, 399 with stable [mild cognitive impairment](#), 99 with dementias other than AD and 251 controls. Cohort B included 105 younger individuals (ages 20 to 34 years) without dementia with CSF samples. Cohort C included 118 patients (ages 60 to 80 years) with mild [cognitive impairment](#) symptoms who underwent imaging and a CSF tap.

The CSF level of A $\beta$ 42 but not total tau and another tau type were lower in APOE carriers with the  $\epsilon$ 4 alternative form of the gene compared with noncarriers regardless of the diagnostic group (cohort A). CSF levels of A $\beta$ 42 differed between patients with AD when compared with controls and those with stable mild cognitive impairment. CSF levels of A $\beta$ 42 and APOE  $\epsilon$ 4 genotype were predictors of AD diagnosis. In cohort B, APOE  $\epsilon$ 4 carrier status did not influence CSF levels of A $\beta$ 42. In cohort C, the APOE  $\epsilon$ 4 genotype did not influence CSF levels of A $\beta$ 42.

"Finally, CSF biomarkers are strongly associated with AD diagnosis and cortical A $\beta$  deposition independently of APOE  $\epsilon$ 4 genotype." Ronald Lautner, M.D., of Sahlgrenska University Hospital, Sweden, and colleagues wrote in their *JAMA Psychiatry* paper.
