Researchers discover why Listeria bacterium is so hard to fight

August 27 2014

The harmful and potentially deadly bacterium Listeria is extremely good at adapting to changes. Now research from University of Southern Denmark uncovers exactly how cunning Listeria is and why it is so hard to fight. The discovery can help develop more efficient ways to combat

the bacteria.

Listeria is a dreaded bacterium that can be found in both unprocessed and processed foods. Over the last few weeks, 28 persons in Denmark have been infected with *Listeria* from processed food, sold in supermarkets. 13 have died.

The bacterium is notoriously difficult to fight because it has an almost uncanny ability to adapt to changes in its surroundings, says Associate Professor Birgitte Kallipolitis, University of Southern Denmark. Together with colleagues from the Department of Biochemistry and Molecular Biology, she has published a study, which in details reveals how this extreme ability to adapt takes place.

The researchers tested how *Listeria* reacts when it is exposed to a number of substances that can normally fight pathogenic bacteria. In the laboratory, *Listeria* was exposed to antibiotics, bile, salt, acid and ethanol, similar to what it often encounters in food, in the human body and during disinfection.

"We knew that *Listeria* can resist these substances, but we did not quite know how," says Birgitte Kallipolitis.

The researchers discovered that *Listeria* used a variety of strategies that enabled them to withstand the substances.

"Generally speaking, *Listeria* must be described as extremely adaptable. It is constantly aware of its surroundings and if the environment changes around it. It reacts instantly and has a number of strategies to withstand threats", says Birgitte Kallipolitis.

The researchers also discovered that *Listeria* is an expert at not attracting unwanted attention from the body's immune system.

"On the one hand, *Listeria* needs to produce some special proteins that enable it to infect the cells in our body. On the other hand, it must ensure that the body's immune system does not detect these proteins. It is vital for *Listeria* to keep a balance between producing enough of these proteins but not so many that they are detected by the immune system – and it masters just that", explains Birgitte Kallipolitis.

When in the lab, the researchers looked at what happened at the microbiological level. It turned out that *Listeria* started producing some special RNA molecules, when they were exposed to antibiotics, bile, salt, acid and ethanol.

"With these RNA molecules the bacteria can adjust how much or how little to produce of various proteins. For example it can downgrade the production of the protein LapB, which it uses to enter our cells. If this production is not downgraded, the bacterium will potentially be detected and fought by the immune system", says Birgitte Kallipolitis.

In other words: *Listeria* can fine-tune the production of the proteins needed to infect our cells to a point where there is exactly enough to sneak through the immune system's defense, but not so many that they are discovered.

The RNA molecules, produced when *Listeria* face dangerous environmental changes, also helps *Listeria* monitor its own cell wall. Antibiotics work by attacking the bacterial cell wall, and when exposed to antibiotics *Listeria* immediately detects that its cell wall is attacked. This enables it to quickly repair its cell wall - and thus become ready for combat again.

"We see this production of RNA molecules only when *Listeria* is exposed to threatening substances in the lab. When there are no threats, *Listeria* does not produce them. This reveals part of the mechanism

behind *Listeria´*s extreme adaptability", concludes Birgitte Kallipolitis.

The understanding of how *Listeria* is able to survive antibiotics, the immune system and disinfecting agents is necessary in order to develop effective means against the life-threatening bacteria.

"Only by looking at what the bacteria themselves do to survive, we can become better at fighting their pathogenicity", says Birgitte Kallipolitis.

She and her colleagues are now investigating whether *Listeria* can be changed into harmless bacteria by removing the RNA molecules.
