(HealthDay)—Adolescents with poor glycemic control of their type 1 diabetes can benefit from therapy delivered either via face to face sessions or videoconferencing, according to a study published online June 1 in *Diabetes Care*.

Michael A. Harris, Ph.D., from the Harold Schnitzer Diabetes Health Center in Portland, Ore., and colleagues assessed how the method of delivery of Behavioral Family Systems Therapy-Diabetes (BFST-D) affected outcomes among adolescents with type 1 diabetes with suboptimal glycemic control ($HbA1c \geq 9.0$ percent). Teens (aged 12 to 18 years) and at least one adult caregiver were randomized to receive

BFST-D face to face in clinic or via Skype [videoconferencing](#).

The researchers found observed no significant between-group differences before or after BFST-D or at follow-up assessments. Collapsing the groups to assess the overall effects of BFST-D revealed that statistically significant improvements in adherence and glycemic control occurred from before to after the intervention. Adherence improvements were maintained at three-month follow-up.

"Delivery of BFST-D via Internet-based videoconferencing is viable for addressing nonadherence and suboptimal glycemic control in adolescents with [type 1 diabetes](#), potentially reducing important barriers to care for youth and families," the authors write.
