

Chemotherapy and quality of life at the end of life

July 23 2015

Chemotherapy for patients with end-stage cancer was associated with worse quality of life near death for patients with a good ability to still perform many life functions, according to an article published online by *JAMA Oncology*.

Physicians have voiced concerns about the benefits of [chemotherapy](#) for patients with [cancer](#) who are nearing death. An American Society of Clinical Oncology (ASCO) expert panel has called chemotherapy use among patients for whom there was no evidence of clinical value the most widespread, wasteful and unnecessary practice in oncology.

Holly G. Prigerson, Ph.D., of Weill Cornell Medical College, New York Presbyterian Hospital, New York, and colleagues examined the association between chemotherapy use and quality of life near death as a function of patients' performance status, which ranks their ability to perform activities such as be ambulatory, do work and handle self-care.

Chemotherapy use (158 patients were receiving it at study enrollment or 50.6 percent) and performance status were assessed at baseline (a median of about four months before death) and 312 patients with progressive metastatic cancer were followed. The majority of patients were men and the average age of patients was 58.6 years.

Study results showed that chemotherapy was not associated with improved quality of life near death for patients with moderate or poor ability to perform functions. But chemotherapy was associated with

worse quality of life near death compared with nonuse of chemotherapy for patients with a good ability to still perform life functions.

"Not only did chemotherapy not benefit patients regardless of performance status, it appeared most harmful to those patients with good performance status. ASCO guidelines regarding chemotherapy use in patients with terminal cancer may need to be revised to recognize the potential harm of chemotherapy use in patients with progressive metastatic disease," the study concludes.
