A rapid-detection Ebola test developed by international scientists including a University of Stirling, Scotland virologist has been deployed following a highly effective pilot project.

Dr Manfred Weidmann, from the University's School of Natural Sciences, was part of a Wellcome Trust project led by the Pasteur Institute of Dakar.

Together, they developed a sophisticated point-of-care saliva test, all contained within a suitcase-sized [mobile laboratory](#). Three mobile labs are now deployed in Senegal and Guinea and a test evaluation of 928 samples showed it performs exceptionally well under field conditions.

"There are more than 25 laboratories in West Africa and everyone is using different tests," said Dr Weidmann. "Ours, which uses a method called recombinase polymerase amplification, was compared to two other tests and results show it can be reliably used without the need for a confirmatory test, and it appears to outperform a widely used WHO recommended test.

"There has been a huge push for robotic testing systems, but they are difficult to establish and expensive to maintain. Our project has successfully developed and deployed a low cost mobile laboratory using a rapid, highly sensitive and specific assay which can be stored at room temperature and operated by local teams with its own energy supply."

Dr Weidmann has also developed a range of assays to detect other mosquito borne viruses, such as Dengue virus and Rift Valley Fever virus.

He added: "Mosquito-borne viruses can affect high numbers of people much faster than Ebola and outbreaks of Dengue virus and Rift Valley Fever virus have recently erupted in West-Africa.
