

Mosquitoes: can't live with 'em, can't live without 'em

April 19 2016, by Catherine Hours , Marlowe Hood

The Zika mosquito

Mozzies. Skeeters. Stingers. Whatever you call them, mosquitoes don't get much love from our species.

And why should they? The buzzing bloodsuckers make us miserable and sick, and would appear to be devoid of any redeeming qualities.

But they are pretty amazing. Mosquitos, let it be said, are...

...primeval and deadly

Mosquitoes were annoying velociraptors and stegosauruses long before a giant meteor wiped out the dinosaurs at the end of the Cretaceous period. The oldest confirmed mozzie fossil is nearly 100 million years old.

Our nagging nemesis is also the most lethal creature in the world, responsible for more than a million human deaths every year, mostly children.

The Anopheles genus carries malaria, which killed some 600,000 people in 2015, according to the World Health Organization.

It also causes painful and sometimes deadly ringworm in dogs, and gathers in swarms thick enough to choke a caribou.

Members of the Aedes genus, meanwhile, spread yellow fever, West Nile virus, dengue, chikungunya, and the Zika virus, which scientists recently confirmed causes severe malformations of foetus brains. Others provoke various strains of encephalitis.

Members of the *Aedes* genus, meanwhile, spread yellow fever, West Nile virus, dengue, chikungunya, and the Zika virus, which scientists recently confirmed causes severe malformations of foetus brains. Others provoke various strains of encephalitis.

There are some 3,500 species in all.

...invasive and nomadic

They are everywhere except Antarctica. With a little help from us, mosquitoes are also highly mobile.

Hitching rides in luggage, cars, cargo ships and planes, many species have spread across the planet thanks to globalisation.

Old tyres and "lucky bamboo" plants are two of their favourite modes of

transportation.

One species, *Aedes albopictus*, has colonised 20 countries in Europe in just the last 25 years, an expansion said to have been helped by global warming.

But skeeters don't move unless they have to.

"If you live next to a place where you are breeding mosquitoes, then they will not go two kilometres (1.2 miles) to find a blood meal, they will go 10 metres (33 feet) from the breeding place to you," explains Eskild Petersen, a professor of tropical diseases at Aarhus University in Denmark.

Our nagging nemesis is also the most lethal creature in the world, responsible for more than a million human deaths every year, mostly children.

They have a short travel span of a few hundred metres, and a lifespan of about two weeks.

And while their wings beat up to 500 times per second, mosquitoes only fly at speeds of about two kilometres per hour.

Salt marsh mosquitos, however, can voyage up to 170 kilometres (100 miles) from their larval breeding ground in search of a meal.

...sexually dimorphous

Which means that males and females are different. Very different.

Only the female—in search of protein for her eggs—consumes blood. Her sometimes virus-infected saliva contains an anti-coagulant to keep things flowing in both directions through her needle-like proboscis.

Males, meanwhile, are vegans, and only sip flower nectar. Whether that is why they only live half as long is unclear.

...useful

"Whatever else they are, mosquitoes have their place in ecosystems," Fabrice Chandre, an expert on insect vectors at the Research Institute for Development in Montpellier, says somewhat grudgingly. As waterbound larvae, mosquitos are filter feeders that consume single-cell algae, and are in turn a favoured food for fish.

As adults, they are tasty snacks for birds, bats and spiders. Weighing in at two to 10 milligrammes it takes a lot to make a meal. But then again, there are a lot of [mosquitoes](#) in the world.

Male mosquitos are important plant pollinators.

...and indestructible

Since the invention of the insecticide DDT in 1939, humans have been trying to wipe mozzies off the face of the Earth. But the insects get used to every new generation of poison, rebounding stronger than ever.

"We simply can't eradicate mosquitos," says Anna-Bella Failloux, an entomologist and mosquito expert at the Institut Pasteur in Paris.

But that doesn't mean we won't keep trying.
