

Favorable outcomes for vitiligo in nivolumab-treated melanoma

August 24 2016

(HealthDay)—For patients with advanced melanoma, vitiligo occurrence

is associated with favorable clinical outcome during nivolumab treatment, according to a study published online Aug. 11 in the *Journal of Dermatology*.

Yasuhiro Nakamura, M.D., Ph.D., from the Saitama Medical University International Medical Center in Japan, and colleagues examined the correlation between vitiligo occurrence and clinical benefit of nivolumab [treatment](#) in advanced melanoma. Data were included for 35 [melanoma](#) patients treated with nivolumab.

The researchers found that 25.7 percent of patients developed vitiligo during treatment. The time to occurrence of vitiligo varied from two to nine months from the start of treatment (mean, 5.2 months). Two of the nine patients who developed vitiligo had a complete response to nivolumab, while two had a partial response. Patients with vitiligo had a significantly higher objective response rate than those without vitiligo (44.4 versus 7.7 percent; $P = 0.027$). For [patients](#) achieving an objective response, the mean time to vitiligo occurrence was significantly less than in those with no response (3.1 versus 6.8 months; $P = 0.004$). There were significant associations for vitiligo occurrence with prolonged progression-free and overall survival (hazard ratios, 0.24 and 0.16, respectively). Vitiligo was not associated with a statistically significant overall survival benefit at the 20-week landmark analysis ($P = 0.28$).

"The occurrence of vitiligo during nivolumab treatment may be correlated with favorable clinical outcome," the authors write.

Two authors disclosed financial ties to the pharmaceutical industry.
