

Cause of cortical malformations targeted by researchers

September 22 2016, by Bill Hathaway

Neurons stained in green are misshapen and misplaced in some cases of epilepsy.

Cortical malformations are a major cause of epileptic seizures and are a hallmark feature of many neurodevelopmental disorders. Expanding upon its recently-published model of cortical malformations, a Yale team lead by neuroscientist Angelique Bordey identified a molecular target that is critical in generating many of the cellular abnormalities

seen in this condition.

Restoring normal signaling through a major regulator of protein synthesis — eIF4E binding protein (4E-BP)—prevented the abnormal positioning, growth, and connectivity of disordered neurons. These findings highlight 4E-BP signaling as a potential drug target in the treatment of seizures and neurological impairments associated with cortical malformations.

The research is published in the *Proceedings of the National Academy of Sciences* and is available Sept. 19.
