

characterised by increased unemployment and lower economic activity, are associated with increased suicide rates, the research is the first to examine the impact of policy-related economic uncertainty on suicide mortality.

Although they found particular impacts in younger and older males, the female population across all ages was found to be resilient to policy-related economic uncertainty.

The researchers recommend that the US government provide information for the general public that communicates clearly that the government is working hard to minimise uncertainty, and that counselling services are available for vulnerable people, particularly younger and older males.

Dr Antonakakis said: "Economic uncertainty is unavoidable. As our results show, it is higher uncertainty that tends to cause increases in suicide rates.

"At times of uncertainty, this means government must not only ensure that it is making strong efforts to ensure lower levels of uncertainty. It must also actively and clearly communicate this in information for the public generally, and younger and older males particularly.

"At the same time, the US government should also ensure that appropriate counselling services are available for vulnerable people, and also communicate this clearly.

"The bottom line of our analysis is that uncertainty should be kept within bounds and attempts to do so must be well-publicised. Of course, at the same time, the importance of other predictors in affecting [suicide rates](#) like unemployment and growth slowdown cannot be ignored, but these variables are likely to improve with reduction in economic policy

uncertainty."

The research is published in *Social Indicators Research*.
