

Many liver transplant candidates have deficits in physical activity that are missed by clinicians

October 3 2016

A new study found that patients waiting for a liver transplant tend to be highly sedentary. Also, patients' self-assessments of their physical activity, and even their doctors' assessments, do not reliably indicate patients' actual physical performance.

Among 53 patients, the average percentages of waking hours spent in sedentary, light, and moderate-to-vigorous activity were 75.9 percent, 18.8 percent, and 4.8 percent, respectively. There was a significantly higher percentage of [sedentary behavior](#) in patients who died while waiting for a transplant compared with those who did not.

"Patients' deficits in [physical activity](#) were often missed using standardized subjective clinical assessments," said Dr. Michael Dunn, lead author of the *Liver Transplantation* article.
