

Exercise may not provide benefit over physical therapy after knee replacement

November 21 2016

In a randomized trial of patients who underwent total knee replacement as a treatment for osteoarthritis, a group program of strengthening and aerobic exercises was not better at alleviating long-term knee pain or overcoming activity limitations compared with usual care, which included physical therapy.

Although most patients experienced less knee pain and improved physical function after undergoing [total knee replacement](#), marked deficits in physical performance measures remained 12 months later.

The findings are published in *Arthritis Care & Research*.
