

Hyperhidrosis tied to prevalence of anxiety, depression

November 19 2016

(HealthDay)—Hyperhidrosis (HH) is associated with increased

prevalence of anxiety and depression, in a HH severity-dependent manner, according to a study published in the December issue of the *Journal of the American Academy of Dermatology*.

Rayekeh Bahar, M.D., from the University of British Columbia in Vancouver, Canada, and colleagues examined the prevalence of [anxiety](#) and depression in patients with or without HH. A total of 2,017 consecutive dermatology outpatients were assessed for depression and anxiety using Patient Health Questionnaire-9 and Generalized Anxiety Disorder-7 scales.

The researchers found that the prevalence of anxiety was 21.3 percent and depression 27.2 percent in patients with HH, compared with 7.5 and 9.7 percent, respectively, in patients without HH (both P demographic factors and presenting skin conditions, in multivariate analysis).

"Both single variant and multivariable analyses showed a significant association between HH and the prevalence of anxiety and [depression](#) in a HH severity-dependent manner," the authors write.
