

Therapeutic family presence key in Tx of acute deterioration in ER

January 31 2017

(HealthDay)—For deteriorating adult patients in the emergency

department, no family presence and physical family presence result in predominantly negative clinician-family-patient interactions, while therapeutic family presence results in positive clinician-family-patient interactions, according to a study published online Jan. 19 in the *Journal of Clinical Nursing*.

Megan J. Youngson, R.N., from Deakin University in Burwood, Australia, and colleagues examined the characteristics and interactions of clinicians, patients, and [family members](#) during management of deteriorating [adult patients](#) in the emergency department. The authors observed five clinical deterioration episodes within a 50-bed [emergency department](#).

The researchers found that while family are present during a patient's episode of deterioration, presence, roles, and engagement describe the interactions between clinicians, family members, and patients. Presence was categorized as no presence, [physical presence](#), or therapeutic presence. During a patient's deterioration episode, clinicians and family members moved through primary, secondary, and tertiary roles. Engagement was either superficial or deep. A complex interplay was identified between presence, roles, and engagement, with each affecting the form of the other variables.

"This study identified three types of presence that occurred during a patient's episode of deterioration," the authors write. "No presence and physical presence resulted in predominantly negative clinician-family-patient interactions, while therapeutic presence resulted in positive clinician-family-patient interactions."
