In a study that followed more than 500 children with attention-deficit/hyperactivity disorder (ADHD) into adulthood, extended use of stimulant medication was linked with suppressed adult height but not with reduced symptoms of ADHD.

The findings suggest that short-term treatment of ADHD with stimulant medication is well justified by benefits that outweigh costs, but long-term treatment may be associated with growth-related costs that may not be balanced by symptom-related benefits.

"The most recently published guidelines (American Academy of Pediatrics, 2011) recommend expanding the diagnosis and treatment beyond school-aged children and using [stimulant medication](#) as first-line treatment for adolescents as well as school-aged children," wrote the authors of *The Journal of Child Psychology and Psychiatry* study. "Since this would increase the average duration of treatment and cumulative ME dose of medication in some individuals, the findings suggest growth-related costs may increase."
