

Food insecurity in early childhood linked to young children's skills in kindergarten

March 21 2017

In the United States, estimates show that a substantial number of children under age 5 live in households that are food insecure. That means that they do not have food, or they lack sufficient quantity or quality of food to fuel a healthy and active lifestyle. A new study has found that children who experience food insecurity in early childhood are more likely to start kindergarten less ready to learn than their peers from homes that are food secure.

The findings come from researchers at Georgetown University and the University of Virginia. They are published in the journal *Child Development*.

"Timing of [food insecurity](#) matters," notes Anna Johnson, assistant professor of psychology at Georgetown University, who led the research. "In our study, food insecurity in infancy and toddlerhood predicted lower cognitive and social-emotional skills in [kindergarten](#), skills that can predict later success in academics and life." Food insecurity during the preschool years was less consistently related to performance in kindergarten, Johnston adds, but when it was, associations were also negative.

In addition to finding that the timing of food insecurity matters, the study found that the number of times (or episodes) a child experienced food insecurity also makes a difference. Researchers considered three episodes—one when [children](#) were 9 months old, one when they were about 2 years old, and one when children were about 4 years old.

"Having more episodes of food insecurity in [early childhood](#)—that is, having three episodes of food insecurity versus one or two—was linked with poorer outcomes in kindergarten across all areas of development," explains Johnson.

The study looked at how food insecurity across the first five years of life affects cognitive and social-emotional skills and behaviors as children start kindergarten. It used nationally representative data (from the Early Childhood Longitudinal Study-Birth Cohort), focusing on the 3,700 low-income households in the sample for whom there were data on food insecurity, as well as children's outcomes. Researchers investigated ties between the timing and intensity of food insecurity in early childhood and children's reading, math, and social-emotional scores in kindergarten. They interviewed parents and assessed children when they were 9 months old, and again when they were 2, 4, and 5 years old, looking at the children's reading and math skills when they started kindergarten, as well as their levels of hyperactivity, conduct problems, and approaches to learning.

This study addresses a gap in understanding associations between food insecurity in early childhood and skills at kindergarten entry. The authors caution that the estimates are noncausal, that is, they cannot rule out the possibility that an unobserved factor caused both increased food insecurity and decreased kindergarten skills, for instance.

"Nevertheless, these findings are worrisome," suggests Anna Markowitz, postdoctoral research associate in the Curry School of Education at the University of Virginia, the study's coauthor. "Increasing the generosity of food assistance programs and ensuring that they reach children whose families are food insecure or at risk for [food insecurity](#) in the earliest years—when children are 2 or younger—could boost the early school success of these vulnerable children."
