

Children with suspected child abuse present to hospital late

April 26 2017

(HealthDay)—Children with suspected child abuse (SCA) present late to

the hospital, and most arrive at hospitals that are not designated pediatric-capable major trauma centers, according to a study published online April 24 in the *Emergency Medicine Journal*.

Ffion C. Davies, M.B.Ch.B., from the University Hospitals of Leicester NHS Trust in the United Kingdom, and colleagues evaluated data (April 2012 to June 2015) from the pediatric database of the national [trauma](#) registry of England and Wales, Trauma Audit and Research Network. They compared the patient pathway for cases of SCA with that of accidental injury (AI).

Overall, 94 percent of the 7,825 children were classified as AI and 6 percent as SCA. The researchers found that compared with AI, SCA cases were younger (median, 0.4 versus 7 years), had a higher Injury Severity Score (median, 16 versus 9), and had higher mortality (5.7 versus 2.2 percent). Other differences included arrival at the [hospital](#) by nonambulance means (74 percent) and delayed presentation from time of injury (median, eight hours versus 1.8 hours for AI). SCA infants were less likely to receive key interventions in a timely manner despite more severe injuries. Few infants (20 percent) arrived at a designated pediatric-capable major trauma center. If needed, secondary transfer to specialist care took a median of 21.6 hours from [injury](#) in SCA cases compared with 13.8 hours for AI cases.

"These data show that [children](#) with major trauma that is inflicted rather than accidental follow a different pathway through the trauma system," the authors write.
