

Odds of a hookah non-smoker taking first puff

May 16 2017

A positive attitude toward and desire to take up hookah smoking are the most likely predictors of a young adult becoming a hookah tobacco smoker, University of Pittsburgh researchers found in the first nationally representative analysis of hookah use by young adults over an extended follow-up period.

The findings indicate that prevention efforts are likely to be more successful if they work to counter the image of hookah tobacco [smoking](#) as a fun activity for socializing and relaxing, rather than focusing on the [negative health consequences](#). The research is published in this month's issue of the journal *Cancer Epidemiology Biomarkers & Prevention*.

"What this study showed us is that young [adults](#) who take up hookah tobacco smoking do so because they think it's cool and attractive, and they weren't dissuaded by the health dangers of smoking," said lead author Jaime E. Sidani, Ph.D., M.P.H., assistant director of Pitt's Center for Research on Media, Technology and Health (CRMTH). "We need to find an effective way to combat those positive attitudes. That might include regulations on advertising and flavorings, coupled with solid counter-messages and educational programs encouraging young adults to think critically about marketing."

Sidani and her colleagues analyzed data from 1,785 adults ages 18 to 30 who reported on their hookah tobacco smoking habits, knowledge and attitudes in 2013 and again 18 months later in 2014. The participants were from across the U.S., equally male and female, and 57 percent

white, 22 percent Hispanic, 13 percent black and 9 percent "other."

Forty-three percent reported having an education level of high school or less, making this study even more notable, as most hookah-related studies focus on college students due to the prevalence of hookah bars near university campuses.

Initially, 69 percent of the participants reported never smoking tobacco from a hookah, also known as a waterpipe, and 25 percent reported having smoked from a hookah at least once. The remaining 6 percent reported smoking from a hookah in the previous 30 days and were characterized as "current" smokers.

After 18 months, 7 percent of people who reported never smoking hookah had transitioned to having smoked at least once, while 4 percent of those who reported ever smoking had transitioned to current users.

Participants who initially reported that they intended to smoke tobacco from a hookah at some point in the future had seven times greater odds of starting to smoke from a hookah in the following 18 months, compared to those who reported they had no plans to use a hookah. And people who reported a positive impression of hookah smoking were nearly twice as likely as their peers to start smoking from one.

However, a negative attitude toward hookah smoking did not have any association with decreased odds of participants becoming hookah smokers, nor did overall knowledge of the harmful components of hookah smoke. This suggests that simply educating [young adults](#) on the negative aspects of [hookah smoking](#) is likely to be ineffective.

"When we extrapolate our findings to the greater population, that translates into nearly 9 million nonsmokers ages 18 to 30 who may have some intention to participate in hookah [tobacco](#) smoking," said Sidani.

"Considering the strong association we found between intention to smoke and becoming a [hookah](#) smoker, it is clear that this is a ripe opportunity to target prevention efforts at this age group."
