A new study finds that delivery of oxygen via high-flow nasal tubes may help patients who experience exacerbations of chronic obstructive pulmonary disease (COPD).

In the 24-patient cross-over trial, short-term use of nasal high-flow cannulae at 35 L/min resulted in lower levels of retained [carbon dioxide](#) compared with standard nasal prongs, but whether this is clinically significant is uncertain.

"These findings suggest that this novel way of delivering [oxygen therapy](#) to patients with an exacerbation of COPD may result in a small reduction in carbon dioxide levels," said Prof. Richard Beasley, co-author of the *Respirology* study. "Further research to assess the clinical utility of nasal high-flow oxygen therapy in patients who experience exacerbations of COPD is now a priority."
