

# Gold specks raise hopes for better cancer treatments

August 7 2017

---

A tiny medical device containing gold specks could boost the effects of cancer medication and reduce its harm, research suggests. Scientists have completed a study which showed that gold increased the effectiveness of drugs used to treat lung cancer cells.

Experts say that the findings could help researchers use the device to reduce side effects of current chemotherapies by precisely targeting [diseased cells](#) without damaging healthy tissue. "We have discovered new properties of [gold](#) that were previously unknown and our findings suggest that the metal could be used to release drugs inside tumours very safely," says Dr Asier Unciti-Broceta.

## Gold nanoparticles

Gold is a safe chemical element and has the ability to accelerate – or catalyse – chemical reactions. Researchers at the Cancer Research UK Edinburgh Centre discovered properties of the precious metal that allow these catalytic abilities to be accessed in living things without any side effects.

Minute fragments, known as [gold nanoparticles](#), were encased in a chemical device by the research team to control these highly-specific reactions in exact locations.

"By developing new, better ways of delivering [cancer drugs](#), studies like

this have the potential to improve cancer treatment and reduce side effects. In particular, it could help improve treatment for [brain tumours](#) and other hard-to-treat cancers. The next steps will be to see if this method is safe to use in people, what its long- and short-term side effects are, and if it's a better way to treat some cancers," says Dr Áine McCarthy.

## Zebrafish

The device was shown to catalyse a directed chemical reaction when implanted in the brain of zebrafish, suggesting it can be used in living animals. Gold nanoparticles also activated anti-cancer medicines that had been applied to [lung cancer cells](#) in a dish, increasing the drugs' effectiveness.

Some 450 people die from cancer every day in the UK. A cancer diagnosis is made every two minutes. Cancer medications are improving, but often damage healthy cells.

"There is still work to do before we can use this on patients, but this study is a step forward. We hope that a similar device in humans could one day be implanted by surgeons to activate chemotherapy directly in tumours and reduce harmful effects to healthy organs," says Dr Asier Unciti-Broceta.
