

Elastography and color doppler improve breast ultrasound

October 30 2017

(HealthDay)—The combination of elastography and color Doppler

ultrasonography (US) with B-mode US in women with dense breasts can increase the positive predictive value of screening and reduce the number of false-positives, according to a study published in the November issue of *Radiology*.

Su Hyun Lee, M.D., from Seoul National University Hospital in Korea, and colleagues investigated the value of the combined use of elastography and color Doppler US with B-mode US for evaluation of screening US-detected breast masses in 1,021 women ([median age](#), 45 years) with [dense breasts](#). The prospective, multicenter study included [asymptomatic women](#) who were referred for screening US between November 2013 and December 2014. Eligible women had a newly detected breast mass at conventional B-mode screening, for which color Doppler US and elastography were performed.

The researchers found that 68 masses were malignant (56 invasive). The addition of elastography and color Doppler US to B-mode US increased the area under the receiver operating characteristic curve from 0.87 to 0.96 (P 0.999). In addition, the [positive predictive value](#) (PPV) increased from 8.9 to 23.2 percent (P

"Addition of elastography and color Doppler US to B-mode US can increase the PPV of screening US in women with dense breasts while reducing the number of false-positive findings without missing cancers," conclude the authors.
