

Both narrowband UVB, psoralen UVA helpful for hand eczema

December 27 2017

(HealthDay)—Both psoralen ultraviolet A (PUVA) and narrowband

ultraviolet B (NBUVB) improve the severity of chronic palmar hand eczema, according to a pilot study published online Dec. 13 in the *British Journal of Dermatology*.

David Brass, from Newcastle Hospitals NHS Trust in the United Kingdom, and colleagues compared immersion PUVA with NBUVB for the [treatment](#) of chronic hand eczema that is unresponsive to topical steroids in 60 patients. The authors performed a [randomized controlled trial](#) in which treatment was given twice weekly for 12 weeks with assessments every four weeks.

Twenty-three of 30 patients in each treatment arm completed the study. The researchers found that five patients in the PUVA arm achieved "clear" and eight achieved "almost clear" on Physician's Global Assessment treatment response, while two in the NBUVB group achieved "clear" and five "almost clear." Median modified Total Lesion and Symptom Score scores were similar between the groups at baseline and at 12 weeks. Similar improvements were seen in the Dermatology Life Quality index for both groups.

"The trial demonstrated that both PUVA and NBUVB improved the severity of chronic palmar hand eczema," the authors write. "The study was not designed to demonstrate superiority of one treatment and a larger adequately powered randomized controlled trial will be required to investigate this."
