

Teens exposed to drug use, mental distress, violence at risk for HIV in adulthood

December 21 2017

The psychological and social risks that adolescents experience can have a lasting impact on adulthood.

When those risks include drug use, mental distress and exposure to violence, they may engage in unsafe sexual behavior that increases their chance of HIV infection, according to a new longitudinal study by the University of Michigan.

"Our findings support the notion that the increasing frequency of [psychosocial risk factors](#) experienced during adolescence may have effects on HIV risk behaviors decades later," said study lead author David Cordova, U-M assistant professor of [social work](#).

Cordova and colleagues conducted the study from September 1994 to May 2013 in Flint, Mich. The participants involved 850 students, mainly African-American, who were asked about their sexual behaviors, mental health, being a victim or witness of violence, and social conditions (family, peer and community factors) beginning at age 14. They were assessed six times during the study until age 32.

One out of four respondents who had a relatively higher frequency of co-occurring psychological and social risk as adolescents were more likely to report unprotected sex with recent partners, as well as sexual intercourse with someone they just met in adulthood.

In addition, they were more likely to use illegal drugs prior to sex, and

had at least four sexual partners. This segment was more vulnerable to HIV risk than those who were part of the low frequency of risk group, which had fewer instances of drug use, violence and [mental distress](#) during adolescence.

Since the study mainly involved African-American respondents, the findings may not be generalized to all adolescent populations, Cordova said.

The findings appear in the journal *AIDS*.
