

Increased prevalence of depression, anxiety after colorectal cancer

April 12 2018

(HealthDay)—The prevalence of depression and anxiety are increased

among survivors of colorectal cancer (CRC), according to a study published online April 6 in *Cancer*.

Floortje Mols, Ph.D., from Tilburg University in the Netherlands, and colleagues examined symptoms of [depression](#) and [anxiety](#) among survivors of CRC. A total of 2,625 patients diagnosed with CRC between 2000 and 2009 completed the Hospital Anxiety and Depression Scale and the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 in 2010, 2011, 2012, and 2013; an age- and sex-matched normative sample comprising 315 individuals completed the questionnaires in 2011.

The researchers found that, compared with the normative sample, patients reported a significantly higher prevalence of depression (19 versus 12.8 percent) and anxiety (20.9 versus 11.8 percent). There was a correlation for longer time since diagnosis with fewer depression symptoms over time; older age and being male were correlated with less anxiety and more depression. Less anxiety and depression were seen in association with being married; a lower educational level and comorbid conditions were correlated with more anxiety and depression. There was a correlation for higher levels of symptoms of anxiety and depression with lower global quality of life and lower physical, role, cognitive, emotional, and social functioning over time.

"Screening and referral are of the utmost importance, especially among those who are single, have a low educational level, and have [comorbid conditions](#)," the authors write.
