Understanding that not all bladder cancers are the same, researchers at the University of North Carolina Lineberger Comprehensive Cancer Center have created a tool that may help them to uncover why only a fraction of patients respond to new immune-based treatments.

In the journal *Cancer Research*, UNC Lineberger's William Y. Kim, MD, Benjamin G. Vincent, MD, and colleagues report they have developed a mouse model of luminal [bladder cancer](#), one of the two subtypes of advanced bladder cancer. The researchers said this model may help them to determine which patients may respond to checkpoint inhibitors, a class of immunotherapy drugs that "remove the brakes" that can keep the immune system from attacking [cancer cells](#).

Five checkpoint inhibitors have been approved for metastatic, or locally advanced, bladder cancer since May 2016, giving patients additional options after standard therapy failed. But studies have shown that less than a quarter of patients will respond to these drugs.

"Not all bladder cancers are the same, and until now, we didn't have the tools to understand biology or look at the therapeutic efficacy of drugs in luminal preclinical models," said Kim, who is an associate professor in the UNC School of Medicine Departments of Genetics, Pharmacology, and Urology. "The biggest impact is that the scientific community now has a mouse model that can be used to understand the biology of these bladder tumors better, and to evaluate promising therapies."

The researchers used their newly created model and an existing model for basal-like bladder cancer, the other subtype of bladder cancer, to examine features that may determine the effectiveness of checkpoint inhibitors.

They studied the immune microenvironment—the [immune cells](#) in and around the tumor—for each subtype. They determined there was lower levels of immune cells in and around luminal tumors, and that this model did not respond as well to PD-1 inhibitors.

They also analyzed the level of neo-antigens present on the two different bladder cancer subtypes. Neoantigens are proteins that sprout on the

surface of cancer tumors as a result of DNA mutations or other alternations in cancer cells. Scientists are interested in using neoantigens to predict response to immunotherapy treatments, or as drug targets.

"We think neoantigens are at least a large reason for why there is an anti-tumor immune response—meaning the body uses the neo-antigens to recognize the tumor as foreign," Kim said. "There's a lot of interest in trying to leverage neo-antigens therapeutically, and so we wanted to see if our [model](#) expressed them."

Vincent's lab used genetic sequencing to predict which abnormal proteins would appear on the surface of the cancer models, and then studied the extent to which the abnormal markers triggered the immune system. They found the luminal subtype had a lower number of markers that were highly immunogenic, or had the ability to trigger the immune system. "Understanding how and why tumors are differentially immunogenic is critical for understanding how to best use therapies that target the immune system in the clinic," Vincent said.

Kim said a future line of research will investigate how neo-antigens help to elicit an immune response, and whether they can leverage their findings to augment the activity of checkpoint inhibitors.

"The models will allow us to mechanistically understand why certain neo-antigens will cooperate with checkpoint inhibitors, and why others don't," Kim said.

Overall, he said the work could help to clarify the best approach for treating patients after their disease has progressed on the standard of care. It also provides a laboratory tool that accounts for bladder cancer being a disease with distinct subtypes.

"We are refining our understanding of cancers, and to make a parallel in

another disease, I'd say to call breast cancer 'breast cancer' nowadays is not appropriate," Kim said "We call it HER2-positive breast cancer, or triple negative breast cancer, because these types are treated differently, and the biology underlying them is different. For bladder cancer, we now understand the same is true—that there are multiple subtypes of disease. We should no longer refer to [bladder cancer](#) as a single disease"
