

Two Ebola patients who received experimental Tx have recovered

August 28 2018

(HealthDay)—Two of the first 10 people to receive an experimental

Ebola treatment have recovered from the highly dangerous disease, Congo's health ministry says.

The patients received a treatment called mAb114, which was isolated from a survivor of an Ebola outbreak in 1995. It was the first of five experimental treatments Congo approved for use in a new outbreak that was declared on Aug. 1, the *Associated Press* reported. The other experimental treatments are ZMapp, Remdesivir, Favipiravir, and Regn3450 - 3471 - 3479. More than 3,400 people have received an experimental Ebola vaccine in this outbreak.

On Saturday, the head of the World Health Organization praised Congo officials for making the experimental treatments available, calling it "a global first, and a ray of hope for people with the disease," the *AP* reported.

To date, there have been 79 confirmed cases in the outbreak, including 42 deaths and 14 patients who have recovered. There are another 28 probable cases. This is Congo's tenth Ebola outbreak. The disease can be fatal in up to 90 percent of cases, depending on the strain.
