

An end to arachnophobia 'just a heartbeat away'

October 30 2018

Treatment of fears like arachnophobia could be reliant on the beat of a heart.

Researchers have discovered that exposing people with phobias to their fear—for examples, spiders for those who have arachnophobia—at the exact time their heart beats, led to the phobia reducing in severity.

Hugo Critchley, Chair of Psychiatry at Brighton and Sussex Medical School (BSMS) and principle investigator, said: "Many of us have phobias of one kind or another—it could be spiders, or clowns or even types of food. Treatment usually involves exposing the person to their fear, but this can take a long time. Our work shows that how we respond

to our fears can depend on whether we see them at the time our heart beats, or between heartbeats. You could say we're within a heartbeat of helping people beat their phobias."

In phobias, disproportionately intense, disabling anxiety is induced by specific situations or triggers.

Treatment is often prolonged and involves a graded exposure to fear-evoking stimuli, but has made some progress in recent years through the use of computerised therapy.

This new research shows that phobias can be treated more effectively by linking computerised therapy to the [patients'](#) own heart rhythms.

Researchers at BSMS had previously revealed how bodily arousal signals that occur with each individual heartbeat can change the emotional impact of potential threats, for example, when experienced during a [heartbeat](#) they can appear greater.

In this proof-of-concept clinical trial, a computerised exposure therapy for [spider phobia](#) was combined with online measurements of heartbeats.

For one group of patients, pictures of spiders were presented in-time with heartbeats (during the signalling of cardiac arousal), while for another patient group, pictures of spiders were presented in-between heartbeats. A third control group saw spiders randomly in the therapy sessions.

Although there was some improvement among all patients, as you would expect in exposure [therapy](#), those individuals exposed to spiders in-time with their own heartbeats showed a greater reductions in self-reported [fear](#) of spiders, anxiety levels and their physiological responses to spiders.

These improvements were also shown to depend on differences in how well an individual patient can accurately feel their own heart beating in their chest, suggesting a further way of tailoring the treatment to benefit each patient.
