In a survey-based study of 9,449 university students at a large, public Midwestern university, misusers of prescription opioid medications were more likely to live off campus, have a lower grade point average, and

exhibit increased impulsivity.

In the *American Journal of Addictions* study, prescription opioid misusers were also more likely to report earlier age of sexual activity and were less likely to use barrier protection during sexual activity.

"This study identifies a number of risk factors for those misusing prescription opioids that can be used to develop and refine prescription opioid misuse screening tools for university health centers," the authors wrote. "It also identifies a number of concurring behaviors that can simultaneously be addressed when prescription [opioid](#) misusers are identified."
