

Monitoring muscles to improve athletic training

October 25 2018, by Zach Winn

Elite athletes understand that to maximize performance, they can't only train hard during workouts—they must also train smart. Unfortunately,

unless you're willing to live in a lab, it can be easier to get real-time information about your car than your body.

Startup Humon is one of a growing number of companies trying to change that with wearable sensors and other technologies. The company's first product, the Hex, measures oxygen in athletes' muscles as they train, and visualizes those data so users can tailor workouts to their body's needs.

"The goal was to create the most useful and personalized training tool today," says Humon CEO and co-founder Alessandro Babini SM '15. "[To achieve that] we needed both amazing, lab-grade data and the expertise of a personal coach combined in a consumer product."

The Hex, a lightweight device that straps onto a user's thigh, determines muscle oxygen levels by emitting light into the muscle tissue and measuring its absorption, in a process called [near-infrared spectroscopy](#). That information is then relayed to a user's phone, smart watch, or laptop via Bluetooth or ANT+ technology and displayed in a simple graph along with personalized insights.

As athletes train, the graph shows them if their muscles are consuming oxygen at a higher rate than what is being supplied, which tells them if their current pace is sustainable.

Babini and his co-founder Daniel Wiese SM '13 Ph.D. '16 got the idea for the Hex in 2015 while working on a class project together at MIT's Sloan School of Management. Wiese was minoring in technology, innovation, and entrepreneurship while pursuing his Ph.D. in mechanical engineering, and Babini was on his way to earning a master's in management studies.

"The only thing we knew is we wanted to start a company centered

around the human body, because we see no scenario in the future in which you'll wake up in the morning knowing as little information about your body as you know today," Babini says.

After deciding to start a company, the founders received support from the Martin Trust Center for MIT Entrepreneurship, which helped them secure office space, connect with mentors, and speak with founders of established companies.

"I hadn't thought about starting a company before, much less had any experience with that process," says Wiese. "I didn't know the first thing about it, so it was just incredible to have all these resources."

They also received a grant while participating in MIT's delta v accelerator and participated in the MIT Fuse program to conduct market research.

"We realized we had very similar views on where we wanted to be in the future, and we knew we wanted to work together," Babini recalls. "So we embarked on this market research project to figure out how to get there."

Finding a target

Elite athletes are relentless in their quest to get even the slightest edge on their competition.

"We realized the early adopters were the athletes because they have a problem, strong purchasing power, and the education to voice their problem," Babini explains. "The problem is they don't have the information they need to optimize their training."

Babini says the only real-time metric athletes have traditionally been able

to track noninvasively has been heart rate, which can be influenced by factors such as caffeine intake and sleep deprivation. The founders wanted to track a metric that offers more value in training sessions, and decided muscle oxygen levels were the best metric of exertion.

Data on muscle oxygen levels can be useful in each stage of a workout: Prior to a training session, athletes can use muscle oxygen data to determine when their muscles are warmed up (helping to prevent injuries); during a training session, such as a long run, they can use the data to determine if their current pace is sustainable; and after a workout, they can use the data to monitor their muscle's recovery and know exactly when they're ready for more exertion—a particularly useful insight during interval training.

Near-infrared spectroscopy, the core technology behind the Hex, has been used to gather physiological data in labs for decades, but the founders sought to make it work seamlessly within an athlete's workout routine. In 2016, after speaking with hundreds of athletes, they began a small pilot trial to get a feel for what the sensor's optimal weight and size would be and how best to display the data. Later that year, they included 250 athletes in a larger trial designed to ensure the Hex solved a significant pain point.

The founders added features to the Hex as they spoke with more athletes, and the company officially started shipping the Hex in February of this year. Wiese likes to break the company's journey to the market into three steps: developing the technology, making it convenient for athletes, and building out the software features.

"All we're doing going forward is software and analytics, mining all of these insights and gleaning everything we can, then communicating that to the user via our app," Wiese says. "We're building out new features all the time and adding functionalities to integrate with user's habits."

Growing engagement

The company markets the Hex as the world's first real-time artificial intelligence coach because the system can prompt users to adjust their pace based on their body's response to current training intensity and tell users when their muscles are ready for another interval set. Additional features will come as the company gathers more data.

Since the launch earlier this year, Humon has sold thousands of devices to users in 46 countries around the world. Babini reports sales are growing 40 percent month-over-month. But the metric the founders say they're most proud of is engagement: The average customer uses the Hex three times a week. (The company is only able to track this metric through the smartphone application.)

Hex is also notable for its accuracy. In April, researchers from Harvard Medical School found that Humon's method of measuring muscle oxygen saturation was up to 96 percent as accurate as the ISS Meta Ox, a stationary device Babini calls the "gold standard" of oxygen monitoring technology.

As the company continues rolling out features for the Hex, it will also unveil plans for a new product early next year. The plans are an indication that, although the founders are happily focused on [athletes](#) for now, they're also mindful of their role in the context of the larger wearables movement.

"We're big believers in the smart clothing industry," Babini says. "We think that's the future of the wearables industry, and [with the Hex] we want to make sure we become a leader in this market using existing sensors and data."
