

# **Super-enhancers: novel target for pancreatic ductal adenocarcinoma**

February 27 2019

---

PDAC cells demonstrated significant binding of different enhancers in PDAC cells than non-cancerous cells, (A) Binding with SOX2, FOXO-1, CDX-2, KLF-4, MED-1, PARD6B, KLF-7, MYC, OCT-4, SOX-9, USP12, INPP5D and (C) with SHH pathway using ChIP-Seq with the H3K27me3 antibody. (B and D) TCGA data also suggested a higher expression of those genes in PDAC compared with normal tissue. Credit: Animesh Dhar

Differential H3K27AC marks were identified at enhancer regions of genes including c-MYC, MED1, OCT-4, NANOG, and SOX2 that can act as super-enhancers (SE), cluster of genes in non-cancerous, cancerous and metastatic PDAC cell lines. GZ17-6.02 affects acetylation of the genes, reduces transcription of major transcription factors, sonic hedgehog pathway proteins, and stem cell markers.

Dr. Animesh Dhar from the Department of Cancer Biology, KU Cancer Center, the University of Kansas Medical Center in Kansas City, KS USA said, "Pancreatic ductal adenocarcinoma is a lethal malignancy and is the fourth leading cause of [cancer](#)-related mortality in the USA, due to its susceptibility to metastasis."

The research revealed how alteration in the transcription and enhancer landscape takes place during discrete stages of disease progression in PDAC mouse model. Thus, identifying novel therapeutic agents targeting enhancers related to disease progression is an imperative need for [cancer research](#).

Co-localization of murine embryonic stem cell genomic sites by the master transcription factors OCT4, SOX2, and NANOG was initially highly predictive of enhancer activity.

As existing defects in cell-signaling pathways allow cancer [cells](#) to alter their normal programs of proliferation, transcription, growth, migration, differentiation, and death, hence reports suggest such reliance on SE-driven transcription for proliferation and survival offers a potent therapeutic mark for the targeting of [cancer cells](#).

Among many pathways of cancer progression that PDAC relies on, anomalous activation of the sonic hedgehog pathway has shown in a variety of human cancers, including, [basal cell carcinoma](#), malignant gliomas, medulloblastoma, leukemias, and cancers of the breast, lung, pancreas, and prostate.

Recent reports suggest that they can target multiple pathways and several cell types including cancer stem cells.

The Dhar research team concluded, "As mentioned earlier in spite of low incidences PDAC is the fourth leading cause of cancer-related mortality because, by the time of diagnosis, more than 80% of cases are locally advanced or distally metastasized, and are not eligible for surgical resection, which is the most effective treatment option."
