

Smokers often misunderstand health risks of smokeless tobacco product, study finds

March 4 2019

American smokers mistakenly think that using snus, a type of moist snuff smokeless tobacco product, is as dangerous as smoking tobacco, according to a Rutgers study.

The study, published in the April 2019 issue of the journal *Addictive Behaviors*, provides new research on what smokers think about snus, a Swedish style product that is popular in Scandinavia, but newer to the United States. Snus—a Swedish word for "snuff"—is a moist powder tobacco that can be sold in a loose form or in small prepacked pouches that users place under the top lip for about 30 minutes. It is typically spit free. About seven in 100 men use some form of smokeless tobacco in the United States, a figure the Centers for Disease Control and Prevention report is on the rise.

While smokeless tobacco products are addictive, contain [cancer](#)-causing chemicals and are linked with cardiovascular and certain cancer risks, products such as snus have comparatively fewer health risks than [smoking](#) when used exclusively—not in tandem with smoking—and may serve as harm-reduction alternatives for smokers unable or unwilling to completely quit tobacco. In Sweden, snus use has been linked to a decrease in [tobacco smoking](#) and smoking-related diseases.

The researchers reviewed how 256 smokers responded to questions about their perceived risk of developing [lung cancer](#), heart disease and [oral cancer](#) from using snus versus cigarettes, and whether there were subgroups of smokers with similar patterns of beliefs. More than 75

percent of the participants smoked daily and about 20 percent had tried smokeless tobacco.

The researchers found that smokers fell into three subgroups based on their beliefs. About 45 percent perceived snus to be as harmful as smoking overall and for all three risks: lung cancer, heart disease and oral cancer. About 38 percent perceived that snus poses less risk for lung cancer and heart disease than cigarettes but had the same oral [cancer risk](#) as cigarettes, and another 17 percent accurately perceived snus to have lower risks for lung cancer but perceived risks for oral cancer and [heart disease](#) to be about the same as that from smoking. Almost 40 percent incorrectly perceived the risk of oral cancer to be higher from snus use than smoking.

"These findings continue to suggest that the public does not understand that combustion escalates the [health risks](#) in tobacco products that are smoked, making them more harmful than non-combusted smokeless tobacco on a continuum of risk," said lead researcher Olivia Wackowski, assistant professor of Health Behavior, Society and Policy at Rutgers School of Public Health and a member of the Rutgers Center for Tobacco Studies and Rutgers Cancer Institute of New Jersey. "They are also significant given that use of Scandinavian snus has not been clearly associated with oral cancer, unlike smoking, which poses a significant risk for oral cancer."

Quitting all tobacco is the best course of action. However, smokers who have not been successful in quitting or who do not want to quit [tobacco](#) entirely may be able to reduce their risks by learning about and switching to a product like snus, Wackowski said. However, this information can be challenging to communicate and is a key area for research work. It's important for smokers to know that the reduced risks may come from completely switching over from smoking to snus use, and not using both products, she said. It's also important that such messaging does not

unintentionally encourage product initiation among non-users, especially youth.
