New research by New York University Steinhardt Associate Professor Susannah Levi finds that children with poorer language skills are at a disadvantage when given tasks or being spoken to by strangers because

they cannot, as easily as their peers, understand speech from people they do not know.

Levi's research evaluated school-aged [children](#) and found that children with high [language](#) skills—a better ability to understand and process language—were able to understand [speech](#) well both by people they knew and were familiar with, as well as strangers who had a similar accent to people they were familiar with. Children with lower language skills understood speech from familiar speakers well, but found it more challenging to understand speakers who they did not know.

"These findings suggest that children who have lower language skills are able to understand speech from familiar speakers, as would be the case with a teacher or parent, but may have a harder time with new speakers, such as a substitute teacher or when interacting with other people in their day to day interactions," said Susannah Levi, NYU Steinhardt professor and the study's lead author.

Levi previously published research showing that when [school-aged children](#) are familiar with someone's voice or accent, they can more accurately and quickly process what a person is saying—a concept known as "familiar talker advantage." The new research, published in the *Journal of Speech, Language and Hearing Research*, by Levi and her co-authors examined how this advantage is impacted by a child's language ability.

With the concept "familiar talker advantage," child listeners naturally store information about what they hear and the way words sound when spoken from people they know. Each time a child is spoken to they go back to this stored information to process and understand words that are spoken to them. This new research demonstrates that children with poorer [language skills](#) have a more difficult time retrieving and processing this information.

The current study included children with a range of language abilities who completed spoken word recognition tasks in which they heard words mixed with [background noise](#) and had to indicate what word they heard. The tasks required children to identify words spoken by voices and accents they were familiar with as well as three unfamiliar voices.
