

Suicide-related ED visits increased in children from 2007 to 2015

April 9 2019

(HealthDay)—From 2007 to 2015, the number of emergency

department visits for suicide attempts (SA) and suicide ideation (SI) doubled among children, according to a research letter published online April 8 in *JAMA Pediatrics*.

Brett Burstein, Ph.D., M.P.H., from the Montreal Children's Hospital, and colleagues performed a repeated cross-sectional analysis of the National Hospital Ambulatory Medical Care Survey emergency department database for 2007 to 2015 to examine trends in emergency department visits for pediatric SA/SI. Data were included for 59,921 unweighted visits, of which 2.8 percent met the inclusion criteria for SA/SI visits.

The researchers found that 43.1 percent of SA/SI visits involved [children](#) aged 5 years to younger than 11 years, and only 2.1 percent of patients were hospitalized. There was an increase in SA/SI visits from 2007 to 2015, from 580,000 to 1.12 million (P for trend = 0.004). No statistically significant change in total emergency department visits was seen during this time (26.9 to 31.8 million; P for trend = 0.67). From 2007 to 2015, there was an increase in SA/SI as a proportion of all pediatric emergency department encounters, from 2.17 to 3.50 percent (P for trend

"Findings suggest a critical need to augment community [mental health resources](#), emergency department physician preparedness, and post-emergency department risk reduction initiatives to decrease the burden of suicide among children," the authors write.
