Increasing the amount of fruit and vegetables people eat lowers their risk of clinical depression, new research has found. The study discovered that eating, for example, four extra portions of fruit and vegetables a day can

boost people's mental health to such an extent that it can offset half the negative psychological impact of divorce and a quarter of the psychological damage of unemployment.

Other studies have used people's subjective responses to surveys to discover a link between eating fruit and vegetables with improved wellbeing. But this is one of only a few studies that has found objective evidence of the association between fruit and vegetables and psychological health.

Dr. Redzo Mujcic, author of the paper alongside Professor Andrew Oswald, of the University of Warwick, said:

"This is an interesting finding and makes the case for an empirical link between fruit and vegetables and improved mental wellbeing more powerful.

"The effect is not small as well. If people eat around seven or eight portions of fruit and vegetables a day the boost in mental wellbeing is as strong as divorce pushing people the other way, to a depressed state.

"We found being made unemployed had a very bad and significant effect on people's mental health, greatly increasing the risk of [depression](#) and anxiety. But eating seven or eight portions of fruit and vegetables a day can reduce that by half.

"And the effect is a lot quicker than the physical improvements you see from a healthy diet. The mental gains occur within 24 months, whereas physical gains don't occur until you are in your 60s.

"This is an important preliminary finding as governments and healthcare policymakers are currently more interested in the determinants of mental ill-health, such as [clinical depression](#) and high levels of anxiety, rather

than people's subjective assessment of their wellbeing as used in previous research."

In the study "Does eating fruit and vegetables also reduce the longitudinal risk of depression and anxiety? A commentary on 'Lettuce be happy,'" published in *Social Science & Medicine*, Dr. Mujcic and Professor Oswald used data from the Household, Income and Labour Dynamics in Australia (HILDA) survey, which has been done annually since 2001. In it respondents are asked if they have been diagnosed with depression or anxiety along with several questions about their diet and lifestyles.

The study used a [representative sample](#) of 7,108 respondents who answered they had not been diagnosed with depression or anxiety in 2007, to see if their diet could predict their chance of depression two years later. The results revealed an inverse relationship between fruit and vegetables and future depression or anxiety—ie the more fruit and vegetables people ate the less likely they were to be diagnosed with a mental illness in later periods.

"If people increase their daily intake of fruit and vegetables from zero to eight they are 3.2 percentage points less likely to suffer depression or anxiety in the next two years," said Dr. Mujcic. "That might not sound much in absolute terms, but the effect is comparable to parts of major life events, like being made unemployed or divorced.

"We tested for reverse-causality—ie whether it might be that depression or [anxiety](#) leads to people eating less [fruit](#) and vegetables—but we found no strong statistical evidence of this.

"However, the next natural step is to do a randomized controlled trial to examine the causal relationship between diet and psychological wellbeing in society."
